**Abstract** A necessary and sufficient condition in terms of lower cut sets are given for the insertion of a contra- $\gamma$ -continuous function between two comparable real-valued functions.

### 1 Introduction

The concept of a preopen set in a topological space was introduced by H.H. Corson and E. Michael in 1964 [5]. A subset A of a topological space  $(X,\tau)$  is called *preopen* or *locally dense* or *nearly open* if  $A\subseteq Int(Cl(A))$ . A set A is called *preclosed* if its complement is preopen or equivalently if  $Cl(Int(A))\subseteq A$ . The term ,preopen, was used for the first time by A.S. Mashhour, M.E. Abd El-Monsef and S.N. El-Deeb [21], while the concept of a , locally dense, set was introduced by H.H. Corson and E. Michael [5].

The concept of a semi-open set in a topological space was introduced by N. Levine in 1963 [18]. A subset A of a topological space  $(X, \tau)$  is called *semi-open* [11] if  $A \subseteq Cl(Int(A))$ . A set A is called *semi-closed* if its complement is semi-open or equivalently if  $Int(Cl(A)) \subseteq A$ .

Recall that a subset A of a topological space  $(X,\tau)$  is called  $\gamma$ -open if  $A\cap S$  is preopen, whenever S is preopen [2]. A set A is called  $\gamma$ -closed if its complement is  $\gamma$ -open or equivalently if  $A\cup S$  is preclosed, whenever S is preclosed.

we have that if a set is  $\gamma$ -open then it is semi-open and preopen.

A generalized class of closed sets was considered by Maki in [20]. He investigated the sets that can be represented as union of closed sets and called them V—sets. Complements of V—sets, i.e., sets that are intersection of open sets are called  $\Lambda$ —sets [20].

Recall that a real-valued function f defined on a topological space X is called A-continuous [24] if the preimage of every open subset of  $\mathbb R$  belongs to A, where A is a collection of subsets of X. Most of the definitions of function used throughout this paper are consequences of the definition of A-continuity. However, for unknown concepts the reader may refer to [6, 12]. In the recent literature many topologists had focused their research in the direction of investigating different types of generalized continuity.

J. Dontchev in [7] introduced a new class of mappings called contra-continuity. A good number of researchers have also initiated different types of contra-continuous like mappings in the papers [1, 4, 9, 10, 11, 13, 14, 23].

Hence, a real-valued function f defined on a topological space X is called  $contra-\gamma-continuous$  (resp. contra-semi-continuous, contra-precontinuous) if the preimage of every open subset of  $\mathbb R$  is  $\gamma-closed$  (resp. semi-closed, preclosed) in X[7].

Results of Katětov [15, 16] concerning binary relations and the concept of an indefinite lower cut set for a real-valued function, which is due to Brooks [3], are used in order to give a necessary and sufficient conditions for the insertion of a contra- $\gamma$ -continuous function between two comparable real-valued functions.

If g and f are real-valued functions defined on a space X, we write  $g \le f$  (resp. g < f) in

```
case g(x) \le f(x) (resp. g(x) < f(x)) for all x in X.
```

The following definitions are modifications of conditions considered in [17].

A property P defined relative to a real-valued function on a topological space is a  $c\gamma-property$  provided that any constant function has property P and provided that the sum of a function with property P and any contra- $\gamma$ -continuous function also has property P. If  $P_1$  and  $P_2$  are  $c\gamma$ -property, the following terminology is used:(i) A space X has the weak  $c\gamma$ -insertion property for  $(P_1, P_2)$  if and only if for any functions g and f on X such that  $g \leq f, g$  has property  $P_1$  and f has property  $P_2$ , then there exists a contra- $\gamma$ -continuous function f such that f if on f if on f if on f if any functions f and f in f in

In this paper, is given a sufficient condition for the weak  $c\gamma$ -insertion property. Also for a space with the weak  $c\gamma$ -insertion property, we give a necessary and sufficient condition for the space to have the  $c\gamma$ -insertion property. Several insertion theorems are obtained as corollaries of these results.

## 2 The Main Result

Before giving a sufficient condition for insertability of a contra- $\gamma$ -continuous function, the necessary definitions and terminology are stated.

Let  $(X,\tau)$  be a topological space, the family of all  $\gamma$ -open,  $\gamma$ -closed, semi-open, semi-closed, preopen and preclosed will be denoted by  $\gamma O(X,\tau)$ ,  $\gamma C(X,\tau)$ ,  $sO(X,\tau)$ ,  $sC(X,\tau)$ ,  $pO(X,\tau)$  and  $pC(X,\tau)$ , respectively.

**Definition 2.1.** Let A be a subset of a topological space  $(X, \tau)$ . We define the subsets  $A^{\Lambda}$  and  $A^{V}$  as follows:

```
A^{\Lambda} = \cap \{O : O \supseteq A, O \in (X, \tau)\} and A^{V} = \cup \{F : F \subseteq A, F^{c} \in (X, \tau)\}. In [8, 19, 22], A^{\Lambda} is called the kernel of A.
```

```
We define the subsets \gamma(A^\Lambda), \gamma(A^V), p(A^\Lambda), p(A^V), s(A^\Lambda) and s(A^V) as follows:  \gamma(A^\Lambda) = \cap \{O:O \supseteq A, O \in \gamma O(X,\tau)\}   \gamma(A^V) = \cup \{F:F \subseteq A, F \in \gamma C(X,\tau)\},   p(A^\Lambda) = \cap \{O:O \supseteq A, O \in pO(X,\tau)\},   p(A^V) = \cup \{F:F \subseteq A, F \in pC(X,\tau)\},   s(A^\Lambda) = \cap \{O:O \supseteq A, O \in sO(X,\tau)\}   and  s(A^V) = \cup \{F:F \subseteq A, F \in sC(X,\tau)\}.   \gamma(A^\Lambda) \text{ (resp. } p(A^\Lambda), s(A^\Lambda) \text{ ) is called the } \gamma - kernel \text{ (resp. } prekernel, semi - kernel) \text{ of } A.
```

The following first two definitions are modifications of conditions considered in [15, 16].

**Definition 2.2.** If  $\rho$  is a binary relation in a set S then  $\bar{\rho}$  is defined as follows:  $x \bar{\rho} y$  if and only if  $y \rho v$  implies  $x \rho v$  and  $u \rho x$  implies  $u \rho y$  for any u and v in S.

**Definition 2.3.** A binary relation  $\rho$  in the power set P(X) of a topological space X is called a *strong binary relation* in P(X) in case  $\rho$  satisfies each of the following conditions:

```
1) If A_i 
ho B_j for any i \in \{1, \ldots, m\} and for any j \in \{1, \ldots, n\}, then there exists a set C in P(X) such that A_i 
ho C and C 
ho B_j for any i \in \{1, \ldots, m\} and any j \in \{1, \ldots, n\}.

2) If A \subseteq B, then A \bar{\rho} B.

3) If A 
ho B, then \gamma(A^{\Lambda}) \subseteq B and A \subseteq \gamma(B^V).
```

The concept of a lower indefinite cut set for a real-valued function was defined by Brooks [3] as follows:

**Definition 2.4.** If f is a real-valued function defined on a space X and if  $\{x \in X : f(x) < \ell\} \subseteq A(f,\ell) \subseteq \{x \in X : f(x) \le \ell\}$  for a real number  $\ell$ , then  $A(f,\ell)$  is called a *lower indefinite cut* set in the domain of f at the level  $\ell$ .

We now give the following main result:

**Theorem 2.1.** Let g and f be real-valued functions on the topological space X, in which  $\gamma$ -kernel sets are  $\gamma$ -open, with  $g \leq f$ . If there exists a strong binary relation  $\rho$  on the power set of X and if there exist lower indefinite cut sets A(f,t) and A(g,t) in the domain of f and g at the level f for each rational number f such that if f and f then f and f then there exists a contra-f-continuous function f defined on f such that f and f and f then there exists a contra-f-continuous function f defined on f such that f and f and f and f are f and f and f are f and f and f are f and f and f are f are f and f are f and f are f and f are f and f are f are f and f are f are f and f are f are f are f and f are f are f are f and f are f are f and f are f are f and f are f are f and

**Proof.** Let g and f be real-valued functions defined on the X such that  $g \leq f$ . By hypothesis there exists a strong binary relation  $\rho$  on the power set of X and there exist lower indefinite cut sets A(f,t) and A(g,t) in the domain of f and g at the level f for each rational number f such that if f and f are the level f for each rational number f such that if f and f are the exist of f are the exist of f and f are the exist of f and f are the exist of f and f are the exist of f are the exist of f and f are the exist of f and f are the exist of f are the exist of f are the exist of f and f are the exist of f are the exist of f and f are the exist of f are the exist of f and f are the exist of f and f are the exist of f are the exist of f and f are the exis

Define functions F and G mapping the rational numbers  $\mathbb Q$  into the power set of X by F(t) = A(f,t) and G(t) = A(g,t). If  $t_1$  and  $t_2$  are any elements of  $\mathbb Q$  with  $t_1 < t_2$ , then  $F(t_1) \ \bar{\rho} \ F(t_2), G(t_1) \ \bar{\rho} \ G(t_2)$ , and  $F(t_1) \ \rho \ G(t_2)$ . By Lemmas 1 and 2 of [16] it follows that there exists a function H mapping  $\mathbb Q$  into the power set of X such that if  $t_1$  and  $t_2$  are any rational numbers with  $t_1 < t_2$ , then  $F(t_1) \ \rho \ H(t_2), H(t_1) \ \rho \ H(t_2)$  and  $H(t_1) \ \rho \ G(t_2)$ .

For any x in X, let  $h(x) = \inf\{t \in \mathbb{Q} : x \in H(t)\}.$ 

We first verify that  $g \le h \le f$ : If x is in H(t) then x is in G(t') for any t' > t; since x is in G(t') = A(g,t') implies that  $g(x) \le t'$ , it follows that  $g(x) \le t$ . Hence  $g \le h$ . If x is not in H(t), then x is not in F(t') for any t' < t; since x is not in F(t') = A(f,t') implies that f(x) > t', it follows that  $f(x) \ge t$ . Hence  $h \le f$ .

Also, for any rational numbers  $t_1$  and  $t_2$  with  $t_1 < t_2$ , we have  $h^{-1}(t_1, t_2) = \gamma(H(t_2)^V) \setminus \gamma(H(t_1)^{\Lambda})$ . Hence  $h^{-1}(t_1, t_2)$  is  $\gamma$ -closed in X, i.e., h is a contra- $\gamma$ -continuous function on X.

The above proof used the technique of theorem 1 in [15].

**Theorem 2.2.** Let  $P_1$  and  $P_2$  be  $c\gamma$ —property and X be a space that satisfies the weak  $c\gamma$ —insertion property for  $(P_1, P_2)$ . Also assume that g and f are functions on X such that g < f, g has property  $P_1$  and f has property  $P_2$ . The space X has the  $c\gamma$ —insertion property for  $(P_1, P_2)$  if and only if there exist lower cut sets  $A(f-g, 3^{-n+1})$  and there exists a decreasing sequence  $\{D_n\}$  of subsets of X with empty intersection and such that for each  $n, X \setminus D_n$  and  $A(f-g, 3^{-n+1})$  are completely separated by contra- $\gamma$ —continuous functions.

**Proof.** Assume that X has the weak  $c\gamma$ -insertion property for  $(P_1,P_2)$ . Let g and f be functions such that g < f,g has property  $P_1$  and f has property  $P_2$ . By hypothesis there exist lower cut sets  $A(f-g,3^{-n+1})$  and there exists a sequence  $(D_n)$  such that  $\bigcap_{n=1}^{\infty} D_n = \emptyset$  and such that for each  $n,X\setminus D_n$  and  $A(f-g,3^{-n+1})$  are completely separated by contra- $\gamma$ -continuous functions. Let  $k_n$  be a contra- $\gamma$ -continuous function such that  $k_n=0$  on  $A(f-g,3^{-n+1})$  and  $k_n=1$  on  $X\setminus D_n$ . Let a function k on X be defined by

$$k(x) = 1/2 \sum_{n=1}^{\infty} 3^{-n} k_n(x).$$

By the Cauchy condition and the properties of contra- $\gamma$ -continuous functions, the function k is a contra- $\gamma$ -continuous function. Since  $\bigcap_{n=1}^{\infty} D_n = \emptyset$  and since  $k_n = 1$  on  $X \setminus D_n$ , it follows that 0 < k. Also 2k < f - g: In order to see this, observe first that if x is in  $A(f - g, 3^{-n+1})$ , then  $k(x) \le 1/4(3^{-n})$ . If x is any point in X, then  $x \notin A(f - g, 1)$  or for some n,

$$x \in A(f-g,3^{-n+1}) - A(f-g,3^{-n});$$

in the former case 2k(x) < 1, and in the latter  $2k(x) \le 1/2(3^{-n}) < f(x) - g(x)$ . Thus if  $f_1 = f - k$  and if  $g_1 = g + k$ , then  $g < g_1 < f_1 < f$ . Since  $P_1$  and  $P_2$  are  $c\gamma$ -properties, then  $g_1$  has property  $P_1$  and  $f_1$  has property  $P_2$ . Since X has the weak  $c\gamma$ -insertion property for  $(P_1, P_2)$ , then there exists a contra- $\gamma$ -continuous function h such that  $g_1 \le h \le f_1$ . Thus g < h < f, it follows that X satisfies the  $c\gamma$ -insertion property for  $(P_1, P_2)$ . (The technique of this proof is by Katětov[15]).

Conversely, let g and f be functions on X such that g has property  $P_1$ , f has property  $P_2$  and g < f. By hypothesis, there exists a contra- $\gamma$ -continuous function h such that g < h < f. We follow an idea contained in Lane [17]. Since the constant function 0 has property  $P_1$ , since f - h has property  $P_2$ , and since X has the  $c\gamma$ -insertion property for  $(P_1, P_2)$ , then there exists a contra- $\gamma$ -continuous function k such that 0 < k < f - h. Let  $A(f - g, 3^{-n+1})$  be any lower cut set for f - g and let  $D_n = \{x \in X : k(x) < 3^{-n+2}\}$ . Since k > 0 it follows that  $\bigcap_{n=1}^{\infty} D_n = \emptyset$ . Since

$$A(f-g,3^{-n+1}) \subseteq \{x \in X : (f-g)(x) \le 3^{-n+1}\} \subseteq \{x \in X : k(x) \le 3^{-n+1}\}$$

and since  $\{x \in X : k(x) \le 3^{-n+1}\}$  and  $\{x \in X : k(x) \ge 3^{-n+2}\} = X \setminus D_n$  are completely separated by contra- $\gamma$ -continuous functions  $\sup\{3^{-n+1},\inf\{k,3^{-n+2}\}\}$ , it follows that for each  $n, A(f-g,3^{-n+1})$  and  $X \setminus D_n$  are completely separated by contra- $\gamma$ -continuous functions.

# 3 Applications

The abbreviations  $c\gamma c$ , cpc and csc are used for contra- $\gamma$ -continuous, contra-precontinuous and contra-semi-continuous, respectively.

Before stating the consequences of theorems 2.1, 2.2, we suppose that X is a topological space whose  $\gamma$ -kernel sets are  $\gamma$ -open.

**Corollary 3.1.** If for each pair of disjoint preopen (resp. semi-open) sets  $G_1, G_2$  of X, there exist  $\gamma$ -closed sets  $F_1$  and  $F_2$  of X such that  $G_1 \subseteq F_1, G_2 \subseteq F_2$  and  $F_1 \cap F_2 = \emptyset$  then X has the weak  $c\gamma$ -insertion property for (cpc, cpc) (resp. (csc, csc)).

**Proof.** Let g and f be real-valued functions defined on X, such that f and g are cpc (resp. csc), and  $g \leq f$ . If a binary relation  $\rho$  is defined by  $A \rho B$  in case  $p(A^{\Lambda}) \subseteq p(B^V)$  (resp.  $s(A^{\Lambda}) \subseteq s(B^V)$ ), then by hypothesis  $\rho$  is a strong binary relation in the power set of X. If  $t_1$  and  $t_2$  are any elements of  $\mathbb Q$  with  $t_1 < t_2$ , then

$$A(f, t_1) \subseteq \{x \in X : f(x) \le t_1\} \subseteq \{x \in X : g(x) < t_2\} \subseteq A(g, t_2);$$

since  $\{x \in X : f(x) \le t_1\}$  is a preopen (resp. semi-open) set and since  $\{x \in X : g(x) < t_2\}$  is a preclosed (resp. semi-closed) set, it follows that  $p(A(f,t_1)^{\Lambda}) \subseteq p(A(g,t_2)^{V})$  (resp.  $s(A(f,t_1)^{\Lambda}) \subseteq s(A(g,t_2)^{V})$ ). Hence  $t_1 < t_2$  implies that  $A(f,t_1) \ \rho \ A(g,t_2)$ . The proof follows from Theorem 2.1.

**Corollary 3.2.** If for each pair of disjoint preopen (resp. semi-open) sets  $G_1, G_2$ , there exist  $\gamma$ -closed sets  $F_1$  and  $F_2$  such that  $G_1 \subseteq F_1$ ,  $G_2 \subseteq F_2$  and  $F_1 \cap F_2 = \emptyset$  then every contraprecontinuous (resp. contra-semi-continuous) function is contra- $\gamma$ -continuous.

**Proof.** Let f be a real-valued contra-precontinuous (resp. contra-semi-continuous) function defined on X. Set g = f, then by Corollary 3.1, there exists a contra- $\gamma$ -continuous function h such that g = h = f.

**Corollary 3.3.** If for each pair of disjoint preopen (resp. semi-open) sets  $G_1, G_2$  of X, there exist  $\gamma$ -closed sets  $F_1$  and  $F_2$  of X such that  $G_1 \subseteq F_1$ ,  $G_2 \subseteq F_2$  and  $F_1 \cap F_2 = \emptyset$  then X has the  $c\gamma$ -insertion property for (cpc, cpc) (resp. (csc, csc)).

**Proof.** Let g and f be real-valued functions defined on the X, such that f and g are cpc (resp. csc), and g < f. Set h = (f+g)/2, thus g < h < f, and by Corollary 3.2, since g and f are contra- $\gamma$ -continuous functions hence h is a contra- $\gamma$ -continuous function.

**Corollary 3.4.** If for each pair of disjoint subsets  $G_1, G_2$  of X, such that  $G_1$  is preopen and  $G_2$  is semi—open, there exist  $\gamma$ —closed subsets  $F_1$  and  $F_2$  of X such that  $G_1 \subseteq F_1, G_2 \subseteq F_2$  and  $F_1 \cap F_2 = \emptyset$  then X have the weak  $c\gamma$ —insertion property for (cpc, csc) and (csc, cpc).

**Proof.** Let g and f be real-valued functions defined on X, such that g is cpc (resp. csc) and f is csc (resp. cpc), with  $g \leq f$ . If a binary relation  $\rho$  is defined by  $A \rho B$  in case  $s(A^{\Lambda}) \subseteq p(B^{V})$  (resp.  $p(A^{\Lambda}) \subseteq s(B^{V})$ ), then by hypothesis  $\rho$  is a strong binary relation in the power set of X.

If  $t_1$  and  $t_2$  are any elements of  $\mathbb{Q}$  with  $t_1 < t_2$ , then

$$A(f, t_1) \subseteq \{x \in X : f(x) \le t_1\} \subseteq \{x \in X : g(x) < t_2\} \subseteq A(g, t_2);$$

since  $\{x \in X : f(x) \le t_1\}$  is a semi-open (resp. preopen) set and since  $\{x \in X : g(x) < t_2\}$  is a preclosed (resp. semi-closed) set, it follows that  $s(A(f,t_1)^{\Lambda}) \subseteq p(A(g,t_2)^{V})$  (resp.  $p(A(f,t_1)^{\Lambda}) \subseteq s(A(g,t_2)^{V})$ ). Hence  $t_1 < t_2$  implies that  $A(f,t_1) \cap A(g,t_2)$ . The proof follows from Theorem 2.1.

Before stating consequences of Theorem 2.2, we state and prove the necessary lemmas.

- **Lemma 3.1.** The following conditions on the space X are equivalent: (i) For each pair of disjoint subsets  $G_1, G_2$  of X, such that  $G_1$  is preopen and  $G_2$  is semi—open,
- there exist  $\gamma$ -closed subsets  $F_1, F_2$  of X such that  $G_1 \subseteq F_1, G_2 \subseteq F_2$  and  $F_1 \cap F_2 = \varnothing$ . (ii) If G is a semi-open (resp. preopen) subset of X which is contained in a preclosed
- (resp. semi-closed) subset F of X, then there exists a  $\gamma$ -closed subset H of X such that  $G \subseteq H \subseteq \gamma(H^{\Lambda}) \subseteq F$ . **Proof.** (i)  $\Rightarrow$  (ii) Suppose that  $G \subseteq F$ , where G and F are semi-open (resp. preopen)
- **Proof.** (i)  $\Rightarrow$  (ii) Suppose that  $G \subseteq F$ , where G and F are semi—open (resp. preopen) and preclosed (resp. semi—closed) subsets of X, respectively. Hence,  $F^c$  is a preopen (resp. semi—open) and  $G \cap F^c = \emptyset$ .
  - By (i) there exists two disjoint  $\gamma$ -closed subsets  $F_1, F_2$  such that  $G \subseteq F_1$  and  $F^c \subseteq F_2$ . But

$$F^c \subseteq F_2 \Rightarrow F_2^c \subseteq F$$
,

and

$$F_1 \cap F_2 = \varnothing \Rightarrow F_1 \subseteq F_2^c$$

hence

$$G \subseteq F_1 \subseteq F_2^c \subseteq F$$

and since  $F_2^c$  is a  $\gamma$ -open subset containing  $F_1$ , we conclude that  $\gamma(F_1^{\Lambda}) \subseteq F_2^c$ , i.e.,

$$G \subseteq F_1 \subseteq \gamma(F_1^{\Lambda}) \subseteq F$$
.

By setting  $H = F_1$ , condition (ii) holds.

(ii)  $\Rightarrow$  (i) Suppose that  $G_1, G_2$  are two disjoint subsets of X, such that  $G_1$  is preopen and  $G_2$  is semi-open.

This implies that  $G_2 \subseteq G_1^c$  and  $G_1^c$  is a preclosed subset of X. Hence by (ii) there exists a  $\gamma$ -closed set H such that  $G_2 \subseteq H \subseteq \gamma(H^{\Lambda}) \subseteq G_1^c$ .

But

$$H \subseteq \gamma(H^{\Lambda}) \Rightarrow H \cap \gamma((H^{\Lambda})^c) = \varnothing$$

and

$$\gamma(H^{\Lambda}) \subseteq G_1^c \Rightarrow G_1 \subseteq \gamma((H^{\Lambda})^c).$$

Furthermore,  $\gamma((H^{\Lambda})^c)$  is a  $\gamma$ -closed subset of X. Hence  $G_2 \subseteq H, G_1 \subseteq \gamma((H^{\Lambda})^c)$  and  $H \cap \gamma((H^{\Lambda})^c) = \emptyset$ . This means that condition (i) holds.

**Lemma 3.2.** Suppose that X is a topological space. If each pair of disjoint subsets  $G_1, G_2$  of X, where  $G_1$  is preopen and  $G_2$  is semi—open, can be separated by  $\gamma$ —closed subsets of X then there exists a contra- $\gamma$ —continuous function  $h: X \to [0,1]$  such that  $h(G_2) = \{0\}$  and  $h(G_1) = \{1\}$ .

**Proof.** Suppose  $G_1$  and  $G_2$  are two disjoint subsets of X, where  $G_1$  is preopen and  $G_2$  is semi-open. Since  $G_1 \cap G_2 = \emptyset$ , hence  $G_2 \subseteq G_1^c$ . In particular, since  $G_1^c$  is a preclosed subset of X containing the semi-open subset  $G_2$  of X, by Lemma 3.1, there exists a  $\gamma$ -closed subset  $H_{1/2}$  such that

$$G_2 \subseteq H_{1/2} \subseteq \gamma(H_{1/2}^{\Lambda}) \subseteq G_1^c$$
.

Note that  $H_{1/2}$  is also a preclosed subset of X and contains  $G_2$ , and  $G_1^c$  is a preclosed subset of X and contains the semi-open subset  $\gamma(H_{1/2}^{\Lambda})$  of X. Hence, by Lemma 3.1, there exists  $\gamma$ -closed subsets  $H_{1/4}$  and  $H_{3/4}$  such that

$$G_2 \subseteq H_{1/4} \subseteq \gamma(H_{1/4}^{\Lambda}) \subseteq H_{1/2} \subseteq \gamma(H_{1/2}^{\Lambda}) \subseteq H_{3/4} \subseteq \gamma(H_{3/4}^{\Lambda}) \subseteq G_1^c$$
.

By continuing this method for every  $t \in D$ , where  $D \subseteq [0,1]$  is the set of rational numbers that their denominators are exponents of 2, we obtain  $\gamma$ -closed subsets  $H_t$  with the property that if  $t_1, t_2 \in D$  and  $t_1 < t_2$ , then  $H_{t_1} \subseteq H_{t_2}$ . We define the function h on X by  $h(x) = \inf\{t : x \in H_t\}$  for  $x \notin G_1$  and h(x) = 1 for  $x \in G_1$ .

Note that for every  $x \in X, 0 \le h(x) \le 1$ , i.e., h maps X into [0,1]. Also, we note that for any  $t \in D, G_2 \subseteq H_t$ ; hence  $h(G_2) = \{0\}$ . Furthermore, by definition,  $h(G_1) = \{1\}$ . It remains only to prove that h is a contra- $\gamma$ -continuous function on X. For every  $\alpha \in \mathbb{R}$ , we have if  $\alpha \le 0$  then  $\{x \in X : h(x) < \alpha\} = \emptyset$  and if  $0 < \alpha$  then  $\{x \in X : h(x) < \alpha\} = \bigcup \{H_t : t < \alpha\}$ , hence, they are  $\gamma$ -closed subsets of X. Similarly, if  $\alpha < 0$  then  $\{x \in X : h(x) > \alpha\} = X$  and if  $0 \le \alpha$  then  $\{x \in X : h(x) > \alpha\} = \bigcup \{\gamma((H_t^{\Lambda})^c) : t > \alpha\}$  hence, every of them is a  $\gamma$ -closed subset. Consequently h is a contra- $\gamma$ -continuous function.

**Lemma 3.3.** Suppose that X is a topological space such that every two disjoint semi—open and preopen subsets of X can be separated by  $\gamma$ —closed subsets of X. The following conditions are equivalent:

- (i) Every countable convering of semi-closed (resp. preclosed) subsets of X has a refinement consisting of preclosed (resp. semi-closed) subsets of X such that for every  $x \in X$ , there exists a  $\gamma$ -closed subset of X containing x such that it intersects only finitely many members of the refinement.
- (ii) Corresponding to every decreasing sequence  $\{G_n\}$  of semi—open (resp. preopen) subsets of X with empty intersection there exists a decreasing sequence  $\{F_n\}$  of preclosed (resp. semi—closed) subsets of X such that  $\bigcap_{n=1}^{\infty} F_n = \emptyset$  and for every  $n \in \mathbb{N}, G_n \subseteq F_n$ .
- **Proof.** (i)  $\Rightarrow$  (ii) Suppose that  $\{G_n\}$  is a decreasing sequence of semi—open (resp. preopen) subsets of X with empty intersection. Then  $\{G_n^c:n\in\mathbb{N}\}$  is a countable covering of semi—closed (resp. preclosed) subsets of X. By hypothesis (i) and Lemma 3.1, this covering has a refinement  $\{V_n:n\in\mathbb{N}\}$  such that every  $V_n$  is a  $\gamma$ -closed subset of X and  $\gamma(V_n^{\Lambda})\subseteq G_n^c$ . By setting  $F_n=\gamma((V_n^{\Lambda})^c)$ , we obtain a decreasing sequence of  $\gamma$ -closed subsets of X with the required properties.
- (ii)  $\Rightarrow$  (i) Now if  $\{H_n: n \in \mathbb{N}\}$  is a countable covering of semi-closed (resp. preclosed) subsets of X, we set for  $n \in \mathbb{N}, G_n = (\bigcup_{i=1}^n H_i)^c$ . Then  $\{G_n\}$  is a decreasing sequence of semi-open (resp. preopen) subsets of X with empty intersection. By (ii) there exists a decreasing sequence  $\{F_n\}$  consisting of preclosed (resp. semi-closed) subsets of X such that  $\bigcap_{n=1}^{\infty} F_n = \emptyset$  and for every  $n \in \mathbb{N}, G_n \subseteq F_n$ . Now we define the subsets  $W_n$  of X in the following manner:

 $W_1$  is a  $\gamma$ -closed subset of X such that  $F_1^c \subseteq W_1$  and  $\gamma(W_1^{\Lambda}) \cap G_1 = \emptyset$ .

 $W_2$  is a  $\gamma$ -closed subset of X such that  $\gamma(W_1^{\Lambda}) \cup F_2^c \subseteq W_2$  and  $\gamma(W_2^{\Lambda}) \cap G_2 = \emptyset$ , and so on. (By Lemma 3.1,  $W_n$  exists).

Then since  $\{F_n^c: n \in \mathbb{N}\}$  is a covering for X, hence  $\{W_n: n \in \mathbb{N}\}$  is a covering for X consisting of  $\gamma$ -closed sets. Moreover, we have

```
(i) \gamma(W_n^{\Lambda}) \subseteq W_{n+1}
```

(ii)  $F_n^c \subseteq W_n$ 

(iii)  $W_n \subseteq \bigcup_{i=1}^n H_i$ .

Now setting  $S_1 = W_1$  and for  $n \ge 2$ , we set  $S_n = W_{n+1} \setminus \gamma(W_{n-1}^{\Lambda})$ .

Then since  $\gamma(W_{n-1}^{\Lambda}) \subseteq W_n$  and  $S_n \supseteq W_{n+1} \setminus W_n$ , it follows that  $\{S_n : n \in \mathbb{N}\}$  consists of  $\gamma$ -closed sets and covers X. Furthermore,  $S_i \cap S_j \neq \emptyset$  if and only if  $|i-j| \leq 1$ . Finally, consider the following sets:

These sets are  $\gamma$ -closed sets, cover X and refine  $\{H_n : n \in \mathbb{N}\}$ . In addition,  $S_i \cap H_j$  can intersect at most the sets in its row, immediately above, or immediately below row.

Hence if  $x \in X$  and  $x \in S_n \cap H_m$ , then  $S_n \cap H_m$  is a  $\gamma$ -closed set containing x that intersects at most finitely many of sets  $S_i \cap H_j$ . Consequently,  $\{S_i \cap H_j : i \in \mathbb{N}, j = 1, \dots, i+1\}$  refines  $\{H_n : n \in \mathbb{N}\}$  such that its elements are  $\gamma$ -closed sets, and for every point in X we can find a  $\gamma$ -closed set containing the point that intersects only finitely many elements of that refinement.

Corollary 3.5. If every two disjoint semi—open and preopen subsets of X can be separated by  $\gamma$ —closed subsets of X, and in addition, every countable covering of semi—closed (resp. preclosed) subsets of X has a refinement that consists of preclosed (resp. semi—closed) subsets of X such that for every point of X we can find a  $\gamma$ —closed subset containing that point such that it intersects only a finite number of refining members then X has the weakly  $c\gamma$ —insertion property for (cpc, csc) (resp. (csc, cpc)).

**Proof.** Since every two disjoint semi—open and preopen sets can be separated by  $\gamma$ —closed subsets of X, therefore by Corollary 3.4, X has the weak  $c\gamma$ —insertion property for (cpc, csc) and (csc, cpc). Now suppose that f and g are real-valued functions on X with g < f, such that g is cpc (resp. csc), f is csc (resp. cpc) and f - g is csc (resp. cpc). For every  $n \in \mathbb{N}$ , set

$$A(f-g,3^{-n+1}) = \{x \in X : (f-g)(x) \le 3^{-n+1}\}.$$

Since f-g is csc (resp. cpc), hence  $A(f-g,3^{-n+1})$  is a semi—open (resp. preopen) subset of X. Consequently,  $\{A(f-g,3^{-n+1})\}$  is a decreasing sequence of semi—open (resp. preopen) subsets of X and furthermore since 0 < f-g, it follows that  $\bigcap_{n=1}^{\infty} A(f-g,3^{-n+1}) = \varnothing$ . Now by Lemma 3.3, there exists a decreasing sequence  $\{D_n\}$  of preclosed (resp. semi—closed) subsets of X such that  $A(f-g,3^{-n+1}) \subseteq D_n$  and  $\bigcap_{n=1}^{\infty} D_n = \varnothing$ . But by Lemma 3.2, the pair  $A(f-g,3^{-n+1})$  and  $X\setminus D_n$  of semi—open (resp. preopen) and preopen (resp. semi—open) subsets of X can be completely separated by contra- $\gamma$ —continuous functions. Hence by Theorem 2.2, there exists a contra- $\gamma$ —continuous function h defined on X such that g < h < f, i.e., X has the weakly  $c\gamma$ —insertion property for (cpc,csc) (resp. (csc,cpc)).
